## Stereo High Fidelity 200 Volt Driver with Mute

### General Description

The LM4702 is a high fidelity audio power amplifier driver designed for demanding consumer and pro-audio applications. Amplifier output power may be scaled by changing the supply voltage and number of output devices. The LM4702 is capable of delivering in excess of 300 watts per channel single ended into an 8 ohm load in the presence of 10% high line headroom and 20% supply regulation.

The LM4702 includes thermal shut down circuitry that activates when the die temperature exceeds 150°C. The LM4702's mute function, when activated, mutes the input drive signal and forces the amplifier output to a quiescent state.

The LM4702 is available in 3 grades that span a wide range of applications and performance levels. The LM4702C is targeted at high volume applications. The LM4702B includes a higher voltage rating along with the tighter specifications. The LM4702A\* (in development) is the premium part with the highest voltage rating, fully specified with limits over voltage and temperature, and is offered in a military 883 compliant TO-3 package.

\* Tentative Max Operating voltage for the LM4702A (in development)

### Key Specifications

■ Wide operating voltage range	
LM4702A* (in development)	±20V to ±100V
LM4702B	±20V to ±100V
LM4702C	±20V to ±75V
■ Equivalent Noise	3μV
■ PSRR	110dB (typ)
■ THD+N (A and B Grades)	0.0003%

### Features

- Very high voltage operation
- Scalable output power
- Minimum external components
- External compensation
- Thermal Shutdown and Mute

### Applications

- AV receivers
- Audiophile power amps
- Pro Audio
- High voltage industrial applications

		at 60Hz / 7kHz			

**Note 1:** All voltages are measured with respect to the ground pins, unless otherwise specified.

**Note 2:** Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. Operating Ratings indicate conditions for which the device is functional, but do not guarantee specific performance limits. Electrical Characteristics state DC and AC electrical specifications under particular test condition which guarantee specific performance limits. This assumes that the device is within the Operating Ratings. Specifications are not guaranteed for parameters where no limit is given. However, the typical value is a good indication of device's performance.

**Note 3:** The maximum power dissipation must be de-rated at elevated temperatures and is dictated by  $T_{JMAX}$ ,  $\theta_{JC}$ , and the ambient temperature  $T_A$ . The maximum allowable power dissipation is  $P_{DMAX} = (T_{JMAX} - T_A)/\theta_{JC}$  or the number given in the Absolute Maximum Ratings, whichever is lower. For the LM4702,  $T_{JMAX} = 150^\circ C$  and the typical  $\theta_{JC}$  is  $1^\circ C/W$ . Refer to the **Thermal Considerations** section for more information.

**Note 4:** Human body model, 100pF discharged through a 1.5k $\Omega$  resistor.

**Note 5:** Machine Model: a 220pF - 240pF discharged through all pins.

**Note 6:** Typical specifications are measured at  $25^\circ C$  and represent the parametric norm.

**Note 7:** Tested limits are guaranteed to National's AOQL (Average Outgoing Quality Level).

**Note 8:** Datasheet min/max specification limits are guaranteed by design, test, or statistical analysis.

**Note 9:** The maximum operating junction temperature is  $150^\circ C$ .

**Note 10:** PCB layout will affect cross talk. It is recommended that input and output traces be separated by as much distance as possible. Return ground traces from outputs should be independent back to a single ground point and use as wide of traces as possible.

**Note 11:** The TA15A is a non-isolated package. The package's metal back and any heat sink to which it is mounted are connected to the Vee potential when using only thermal compound. If a mica washer is used in addition to thermal compound,  $\theta_{CS}$  (case to sink) is increased, but the heat sink will be electrically isolated from Vee.

## Application Information

### MUTE FUNCTION

The mute function of the LM4702 is controlled by the amount of current that flows into the mute pin. If there is less than 1mA of current flowing into the mute pin, the part will be in mute. This can be achieved by shorting the mute pin to ground or by floating the mute pin. If there is between 1mA and 2mA of current flowing into the mute pin, the part will be in "play" mode. This can be done by connecting a power supply (Vmute) to the mute pin through a resistor (Rm). The current into the mute pin can be determined by the equation  $I_{\text{mute}} = (V_{\text{mute}} - 2.9) / R_m$ . For example, if a 5V power supply is connected through a 1.4k resistor to the mute pin, then the mute current will be 1.5mA, at the center of the specified range. It is also possible to use Vcc as the power supply for the mute pin, though Rm will have to be recalculated accordingly. It is not recommended to flow more than 2mA of current into the mute pin because damage to the LM4702 may occur.

It is highly recommended to switch between mute and "play" modes rapidly. This is accomplished most easily through using a toggle switch that alternatively connects the mute pin through a resistor to either ground or the mute pin power supply. Slowly increasing the mute current may result in undesired voltages on the outputs of the LM4702, which can damage an attached speaker.

### THERMAL PROTECTION

The LM4702 has a sophisticated thermal protection scheme to prevent long-term thermal stress of the device. When the temperature on the die exceeds 150°C, the LM4702 shuts down. It starts operating again when the die temperature drops to about 145°C, but if the temperature again begins to rise, shutdown will occur again above 150°C. Therefore, the device is allowed to heat up to a relatively high temperature if the fault condition is temporary, but a sustained fault will cause the device to cycle in a Schmitt Trigger fashion between the thermal shutdown temperature limits of 150°C and 145°C. This greatly reduces the stress imposed on the IC by thermal cycling, which in turn improves its reliability under sustained fault conditions.

Since the die temperature is directly dependent upon the heat sink used, the heat sink should be chosen so that thermal shutdown is not activated during normal operation. Using the best heat sink possible within the cost and space constraints of the system will improve the long-term reliability of any power semiconductor device, as discussed in the **Determining the Correct Heat Sink** section.

### POWER DISSIPATION AND HEAT SINKING

When in "play" mode, the LM4702 draws a constant amount of current, regardless of the input signal amplitude. Consequently, the power dissipation is constant for a given supply voltage and can be computed with the equation  $P_{\text{DMAX}} = I_{\text{CC}} * (V_{\text{CC}} - V_{\text{EE}})$ . For a quick calculation of  $P_{\text{DMAX}}$ , approximate the current to be 25mA and multiply it by the total supply voltage (the current varies slightly from this value over the operating range).

### DETERMINING THE CORRECT HEAT SINK

The choice of a heat sink for a high-power audio amplifier is made entirely to keep the die temperature at a level such that the thermal protection circuitry is not activated under normal circumstances.

The thermal resistance from the die to the outside air,  $\theta_{\text{JA}}$  (junction to ambient), is a combination of three thermal resistances,  $\theta_{\text{JC}}$  (junction to case),  $\theta_{\text{CS}}$  (case to sink), and  $\theta_{\text{SA}}$  (sink to ambient). The thermal resistance,  $\theta_{\text{JC}}$  (junction to case), of the LM4702T is 0.8°C/W. Using Thermalloy Thermacote thermal compound, the thermal resistance,  $\theta_{\text{CS}}$  (case to sink), is about 0.2°C/W. Since convection heat flow (power dissipation) is analogous to current flow, thermal resistance is analogous to electrical resistance, and temperature drops are analogous to voltage drops, the power dissipation out of the LM4702 is equal to the following:

$$P_{\text{DMAX}} = (T_{\text{JMAX}} - T_{\text{AMB}}) / \theta_{\text{JA}} \quad (1)$$

where  $T_{\text{JMAX}} = 150^\circ\text{C}$ ,  $T_{\text{AMB}}$  is the system ambient temperature and  $\theta_{\text{JA}} = \theta_{\text{JC}} + \theta_{\text{CS}} + \theta_{\text{SA}}$ .

Once the maximum package power dissipation has been calculated using equation 2, the maximum thermal resistance,  $\theta_{\text{SA}}$ , (heat sink to ambient) in °C/W for a heat sink can be calculated. This calculation is made using equation 4 which is derived by solving for  $\theta_{\text{SA}}$  in equation 3.

$$\theta_{\text{SA}} = [(T_{\text{JMAX}} - T_{\text{AMB}}) - P_{\text{DMAX}}(\theta_{\text{JC}} + \theta_{\text{CS}})] / P_{\text{DMAX}} \quad (2)$$

Again it must be noted that the value of  $\theta_{\text{SA}}$  is dependent upon the system designer's amplifier requirements. If the ambient temperature that the audio amplifier is to be working under is higher than 25°C, then the thermal resistance for the heat sink, given all other things are equal, will need to be smaller.

### PROPER SELECTION OF EXTERNAL COMPONENTS

Proper selection of external components is required to meet the design targets of an application. The choice of external component values that will affect gain and low frequency response are discussed below.

The gain of each amplifier is set by resistors  $R_f$  and  $R_i$  for the non-inverting configuration shown in Figure 1. The gain is found by Equation (3) below:

$$A_v = 1 + R_f / R_i \quad (\text{V/V}) \quad (3)$$

For best noise performance, lower values of resistors are used. A value of 1kΩ is commonly used for  $R_i$  and then setting the value of  $R_f$  for the desired gain. For the LM4702 the gain should be set no lower than 26dB. Gain settings below 26dB may experience instability.

The combination of  $R_i$  with  $C_i$  (see Figure 1) creates a high pass filter. The low frequency response is determined by these two components. The -3dB point can be found from Equation (4) shown below:

$$f_i = 1 / (2\pi R_i C_i) \quad (\text{Hz}) \quad (4)$$

If an input coupling capacitor is used to block DC from the inputs as shown in Figure 5, there will be another high pass filter created with the combination of  $C_{\text{IN}}$  and  $R_{\text{IN}}$ . When using an input coupling capacitor  $R_{\text{IN}}$  is needed to set the DC

## Application Information (Continued)

bias point on the amplifier's input terminal. The resulting -3dB frequency response due to the combination of  $C_{IN}$  and  $R_{IN}$  can be found from Equation (5) shown below:

$$f_{IN} = 1 / (2\pi R_{IN} C_{IN}) \text{ (Hz)} \quad (5)$$

With large values of  $R_{IN}$  oscillations may be observed on the outputs when the inputs are left floating. Decreasing the value of  $R_{IN}$  or not letting the inputs float will remove the oscillations. If the value of  $R_{IN}$  is decreased then the value of  $C_{IN}$  will need to increase in order to maintain the same -3dB frequency response.

### AVOIDING THERMAL RUNAWAY WHEN USING BIPOLAR OUTPUT STAGES

When using a bipolar output stage with the LM4702 (as in Figure 1), the designer must beware of thermal runaway. Thermal runaway is a result of the temperature dependence of  $V_{be}$  (an inherent property of the transistor). As temperature increases,  $V_{be}$  decreases. In practice, current flowing through a bipolar transistor heats up the transistor, which lowers the  $V_{be}$ . This in turn increases the current again, and the cycle repeats. If the system is not designed properly, this positive feedback mechanism can destroy the bipolar transistors used in the output stage.

One of the recommended methods of preventing thermal runaway is to use a heat sink on the bipolar output transistors. This will keep the temperature of the transistors lower. A second recommended method is to use emitter degeneration resistors (see  $R_{e1}$ ,  $R_{e2}$ ,  $R_{e3}$ ,  $R_{e4}$  in Figure 1). As current increases, the voltage across the emitter degeneration resistor also increases, which decreases the voltage across the base and emitter. This mechanism helps to limit the current and counteracts thermal runaway.

A third recommended method is to use a "Vbe multiplier" to bias the bipolar output stage (see Figure 1). The Vbe multiplier consists of a bipolar transistor ( $Q_{mult}$ , see Figure 1) and two resistors, one from the base to the collector ( $R_{b2}$ ,  $R_{b4}$ , see Figure 1) and one from the base to the emitter ( $R_{b1}$ ,  $R_{b3}$ , see Figure 1). The voltage from the collector to the emitter (also the bias voltage of the output stage) is  $V_{bias} = V_{be}(1 + R_{b2}/R_{b1})$ , which is why this circuit is called the Vbe multiplier. When Vbe multiplier transistor ( $Q_{mult}$ , see Figure 1) is mounted to the same heat sink as the bipolar output transistors, its temperature will track that of the output transistors. Its  $V_{be}$  is dependent upon temperature as well, and so it will draw more current as the output transistors heat it up. This will limit the base current into the output transistors, which counteracts thermal runaway.

1.4	04/26/04	Edited Limit values on the LM4702B spec table.
1.5	08/09/06	Released the D/S to the WEB with the LM4702B data.
1.6	09/19/06	Removed the "Overture R" from the document title, then released the D/S to the WEB

## IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
